# On the category of comodules over corings

Robert Wisbauer

#### Abstract

It is well known that the category  $\mathcal{M}^{\mathcal{C}}$  of right comodules over an A-coring  $\mathcal{C}$ , A an associative ring, is a subcategory of the category of left modules  $*_{\mathcal{C}}\mathcal{M}$  over the dual ring  $*\mathcal{C}$ . The main purpose of this note is to show that  $\mathcal{M}^{\mathcal{C}}$  is a full subcatgeory in  $*_{\mathcal{C}}\mathcal{M}$  if and only if  $\mathcal{C}$  is locally projective as a left A-module.

### 1 Introduction

For any coassociative coalgebra C over a commutative ring R, the convolution product turns the dual module  $C^* = \operatorname{Hom}_R(C, R)$  into an associative R-algebra. The category  $\mathcal{M}^C$  of right comodules is an additive subcategory of the category  $_{C^*}\mathcal{M}$  of left  $C^*$ -modules.  $\mathcal{M}^C$  is an abelian (in fact a Grothendieck) category if and only if C is flat as an R-module. Moreover,  $\mathcal{M}^C$  coincides with  $_{C^*}\mathcal{M}$  if and only if C is finitely generated and projective as an R-module (e.g. [11, Corollary 33]).

In case C is projective as an R-module,  $\mathcal{M}^C$  is a full subcategory of  $_{C^*}\mathcal{M}$  and coincides with  $\sigma_{[C^*}C]$ , the category of submodules of C-generated  $C^*$ -modules (e.g. [9, 3.15, 4.3]). It was well understood from examples that projectivity of C as an R-module was not necessary to achieve  $\mathcal{M}^C = \sigma_{[C^*}C]$  and that the equality holds provided C satisfies the  $\alpha$ -condition, i.e., the canonical maps  $N \otimes_R C \to \operatorname{Hom}_{\mathbb{Z}}(C^*, N)$  are injective for all R-modules N (e.g. [1, Satz 2.2.13], [2, Section 2], [10, 3.2]). It will follow from our results that this condition is in fact equivalent to  $\mathcal{M}^C = \sigma_{[C^*}C]$  and also to C being locally projective as an R-module.

We do investigate the questions and results mentioned above in the more general case of comodules over any *A*-coring, *A* an associative ring, and it will turn out that the above observations remain valid almost literally in this extended setting.

## 2 Some module theory

Let A be any associative ring with unit and denote  $(-)^* = \operatorname{Hom}_A(-, A)$ . We write  ${}_{A}\mathcal{M}(\mathcal{M}_A)$  for the category of unital left (right) A-modules. I (or  $I_N$ ) will denote the identity map (of the module N).

### **2.1. Canonical maps.** For any left A-module K, consider the maps

For any right A-module N define the maps

$$\begin{array}{rcl} \alpha_{N,K} &\colon & N \otimes_A K &\to \operatorname{Hom}_{\mathbb{Z}}(K^*,N), & n \otimes k \mapsto & [f \mapsto nf(k)], \\ \psi_N &\colon & N \otimes_A A^{K^*} &\to N^{K^*}, & n \otimes & (a_f)_{f \in K^*} \mapsto & (na_f)_{f \in K^*}. \end{array}$$

By the identification  $\operatorname{Map}(K^*, N) = N^{K^*}$  we have the commutative diagram

**2.2.** Injectivity of  $\alpha_{N,K}$ . We stick to the notation above.

- (1) The following are equivalent:
  - (a)  $\alpha_{N,K}$  is injective;

(b) for 
$$u \in N \otimes_A K$$
,  $(I \otimes f)(u) = 0$  for all  $f \in K^*$ , implies  $u = 0$ .

(2) The following are equivalent:

- (a) For every finitely presented right A-module N,  $\alpha_{N,K}$  is injective;
- (b)  $\tilde{\varphi}_K : K \to A^{K^*}$  is a pure monomorphism.

*Proof.* (1) Let  $u = \sum_{i=1}^{r} n_i \otimes k_i \in N \otimes_A K$ . Then  $(I \otimes f)(u) = \sum_{i=1}^{r} n_i f(k_i) = 0$ , for all  $f \in K^*$  if and only if  $u \in \text{Ke } \alpha_{N,K}$ .

(2) For N finitely presented,  $\psi_N$  is injective (bijective) and so  $\alpha_{N,K}$  is injective if and only if  $I_N \otimes \tilde{\varphi}_K$  is injective. Injectivity of  $I_N \otimes \tilde{\varphi}_K$  for all finitely presented N characterizes  $\tilde{\varphi}_K$  as a pure monomorphism (e.g., [8, 34.5]).

We say that K satisfies the  $\alpha$ -condition provided  $\alpha_{N,K}$  is injective for all right A-modules N. Such modules are named universally torsionless (UTL) in [4] and we recall some of their characterizations.

The module K is called *locally projective* (see [12]) if, for any diagram of left A-modules with exact lines

$$\begin{array}{cccc} 0 \longrightarrow F & \stackrel{i}{\longrightarrow} & K \\ & & & & \downarrow^{g} \\ & & L \stackrel{f}{\longrightarrow} & N \longrightarrow 0 \end{array}$$

where F is finitely generated, there exists  $h: K \to L$  such that  $g \circ i = f \circ h \circ i$ .

Clearly every projective module is locally projective. From Garfinkel [4, Theorem 3.2] and Huisgen-Zimmermann [12, Theorem 2.1] we have the following characterizations of these modules which are also studied in Ohm-Bush [5] (as *trace modules*), and in Raynaud-Gruson [6] (as *modules plats et strictement de Mittag-Leffler*).

**2.3. Locally projective modules.** For the left A-module K, the following are equivalent:

- (a) K is locally projective;
- (b) K is a pure submodule of a locally projective module;
- (c)  $\alpha_{N,K}$  is injective, for any right A-module N;
- (d)  $\alpha_{N,K}$  is injective, for any cyclic right A-module N;
- (e) for each  $m \in K$ , we have  $m \in K^*(m)K$ ;
- (f) for each finitely generated submodule  $i: F \to K$ , there exists  $n \in \mathbb{N}$ and maps  $\beta: \mathbb{R}^n \to K$ ,  $\gamma: K \to \mathbb{R}^n$  with  $\beta \circ \gamma \circ i = i$ .

Recall the following observations. Notice that for a right noetherian ring A, every product of copies of A is locally projective as left A-module (e.g. [12, Corollary 4.3]).

#### **2.4.** Corollary. Let K be a left A-module.

- (1) Every locally projective module is flat and a pure submodule of some product  $A^{\Lambda}$ ,  $\Lambda$  some set.
- (2) If K is finitely generated, or A is left perfect, then K is locally projective if and only if K is projective.

- (3) For a right noetherian ring A, the following are equivalent:
  - (a) K is locally projective;
  - (b) K is a pure submodule of a product  $A^{\Lambda}$ ,  $\Lambda$  some set.

The following facts from general category theory will be helpful (e.g., [7]). In any category  $\mathcal{A}$ , a morphism  $f : A \to B$  is called a *monomorphism* if for any morphisms  $g, h : C \to A$  the identity  $f \circ g = f \circ h$  implies g = h.

In an additive category  $\mathcal{A}$  a morphism  $\gamma : K \to A$  is called a *kernel* of  $f : A \to B$  provided  $f \circ \gamma = 0$  and, for every  $g : C \to A$  with  $f \circ g = 0$ , there is exactly one  $h : C \to K$  such that  $g = \gamma \circ h$ .

Recall the following well-known (and easily proved) observations.

**2.5.** Monomorphisms. Let  $\mathcal{A}$  be any catgeory and  $f : A \to B$  a morphism in  $\mathcal{A}$ . The following are equivalent:

- (a) f is a monomorphism;
- (b) the map  $Mor(L, f) : Mor(L, A) \to Mor(L, B), g \mapsto f \circ g$ , is injective, for any  $L \in A$ .

If A is additive and has kernels, then (a)-(b) are equivalent to:

(c) for the kernel  $\gamma: K \to A$  of f, K = 0.

The basic properties of adjoint functors will be helpful.

**2.6.** Adjoint functors. Let  $\mathcal{A}$  and  $\mathcal{B}$  be any categories. Assume a functor  $F : \mathcal{A} \to \mathcal{B}$  is right adjoint to a functor  $G : \mathcal{B} \to \mathcal{A}$ , i.e.,

$$\operatorname{Mor}_{\mathcal{B}}(Y, F(X)) \simeq \operatorname{Mor}_{\mathcal{A}}(G(Y), X)), \text{ for any } X \in \mathcal{A}, Y \in \mathcal{B}.$$

Then

- (1) F preserves monomorphisms and products,
- (2) G preserves epimorphisms and coproducts.

For the study of comodules the following type of module categories is of particular interest.

**2.7. The category**  $\sigma[K]$ . For any left *A*-module *K* we denote by  $\sigma[K]$  the full subcategory of  ${}_{A}\mathcal{M}$  whose objects are submodules of *K*-generated modules. This is the smallest full Grothendieck subcategory of  ${}_{A}\mathcal{M}$  containing *K* (see [8]).

 $\sigma[K]$  coincides with  ${}_{A}\mathcal{M}$  if and only if A embeds into some (finite) coproduct of copies of K. This happens, for example, when K is a faithful A-module which is finitely generated as a module over its endomorphism ring (see [8, 15.4]).

The trace functor  $\mathcal{T}^K : {}_A\mathcal{M} \to \sigma[K]$ , which sends any  $X \in {}_A\mathcal{M}$  to

$$\mathcal{T}^{K}(X) := \sum \{ f(N) \mid N \in \sigma[K], \ f \in \operatorname{Hom}_{A}(N, X) \},\$$

is right adjoint to the inclusion functor  $\sigma[K] \to {}_{A}\mathcal{M}$  (e.g., [8, 45.11]). Hence, by 2.6, for any family  $\{N_{\lambda}\}_{\Lambda}$  of modules in  $\sigma[K]$ , the product in  $\sigma[K]$  is

$$\prod_{\Lambda}^{K} N_{\lambda} = \mathcal{T}^{K}(\prod_{\Lambda} N_{\lambda}),$$

where the unadorned  $\prod$  denotes the usual (cartesian) product of A-modules.

It also follows from 2.6 that for  $\{N_{\lambda}\}_{\Lambda}$  in  $\sigma[K]$  the coproduct in  $\sigma[K]$  and the coproduct in  $_{A}\mathcal{M}$  coincide.

## 3 Corings and comodules

As before, let A be any associative ring with unit.

**3.1. Corings and their duals.** An *A*-coring is an (A, A)-bimodule C with (A, A)-bimodule maps (comultiplication and counit)

$$\underline{\Delta}: \mathcal{C} \to \mathcal{C} \otimes_A \mathcal{C}, \quad \underline{\varepsilon}: \mathcal{C} \to A,$$

satisfying the identities

$$(I \otimes \underline{\Delta}) \circ \underline{\Delta} = (\underline{\Delta} \otimes I) \circ \underline{\Delta}, \quad (I \otimes \underline{\varepsilon}) \circ \underline{\Delta} = I = (\underline{\varepsilon} \otimes I) \circ \underline{\Delta}.$$

For elementwise description of these maps we adopt the  $\Sigma$ -notation, writing for  $c \in \mathcal{C}$ ,

$$\underline{\Delta}(c) = \sum c_{\underline{1}} \otimes c_{\underline{2}}.$$

Then coassociativity of  $\underline{\Delta}$  is written as

$$\sum \underline{\Delta}(c_{\underline{1}}) \otimes c_{\underline{2}} = \sum c_{\underline{1}\underline{1}} \otimes c_{\underline{1}\underline{2}} \otimes c_{\underline{2}} = \sum c_{\underline{1}} \otimes c_{\underline{2}\underline{1}} \otimes c_{\underline{2}\underline{2}} = \sum c_{\underline{1}} \otimes \underline{\Delta}(c_{\underline{2}}),$$

and the conditions on the counit are

$$\sum \underline{\varepsilon}(c_{\underline{1}})c_{\underline{2}} = c = \sum c_{\underline{1}}\underline{\varepsilon}(c_{\underline{2}}).$$

Of course, when A is commutative and ac = ca for all  $a \in A$ ,  $c \in C$ , the coring C is just a *coalgebra* in the usual sense.

For any A-coring  $\mathcal{C}$ , the maps  $\mathcal{C} \to A$  may be right A-linear or left A-linear and we denote these by

$$\mathcal{C}^* := \operatorname{Hom}_{-A}(\mathcal{C}, A), \quad {}^*\mathcal{C} := \operatorname{Hom}_{A-}(\mathcal{C}, A),$$

and for bilinear maps we have  $\operatorname{Hom}_{AA}(\mathcal{C}, A) = {}^*\mathcal{C} \cap \mathcal{C}^*$ .

Both  $\mathcal{C}^*$  and  $^*\mathcal{C}$  can be turned to associative rings with unit  $\underline{\varepsilon}$  by the (convolution) products

- (1) for  $f, g \in \mathcal{C}^*$ , and  $c \in \mathcal{C}$  put  $f^* g(c) = \sum g(f(c_1)c_2)$ ,
- (2) for  $f, g \in {}^*\mathcal{C}$ , and  $c \in \mathcal{C}$  put  $f * {}^l g(c) = \sum f(c_1g(c_2))$ .

Notice that for  $f, g \in {}^*\mathcal{C} \cap \mathcal{C}^*$  this yields

$$f * g(c) = \sum f(c_{\underline{1}})g(c_{\underline{2}}),$$

a formula which is well known from coalgebras.

It is easily verified that the maps

$$\iota_l : A \to {}^*\mathcal{C}, \ a \mapsto [c \mapsto \underline{\varepsilon}(c)a], \text{ and } \quad \iota_r : A \to \mathcal{C}^*, \ a \mapsto [c \mapsto a\underline{\varepsilon}(c)],$$

are ring anti-morphisms and hence we may consider left \*C-modules as right A-modules and right  $C^*$ -modules as left A-modules.

**3.2. Right comodules.** Let  $\mathcal{C}$  be an A-coring and M a right A-module. An A-linear map  $\varrho_M : M \to M \otimes_A \mathcal{C}$  is called a *coaction* on M, and it is said to be *counital* and *coassociative* provided

$$(I \otimes \underline{\varepsilon}) \circ \varrho_M = I$$
, and  $(I \otimes \underline{\Delta}) \circ \varrho_M = (\varrho_M \otimes I) \circ \varrho_M$ .

A right C-comodule is a right A-module with a counital coassociative coaction.

A morphism of right  $\mathcal{C}$ -comodules  $f: M \to N$  is an A-linear map such that

$$\varrho_N \circ f = (f \otimes I) \circ \varrho_M$$

We denote the set of comodule morphisms between M and N by  $\operatorname{Hom}^{\mathcal{C}}(M, N)$ . It is easy to show that this is an abelian group and hence the category  $\mathcal{M}^{\mathcal{C}}$ , formed by right  $\mathcal{C}$ -comodules and comodule morphisms, is additive. For any right A-module X, the tensor product  $X \otimes_A C$  is a right Ccomodule by

$$I \otimes \underline{\Delta} : X \otimes_A \mathcal{C} \to X \otimes_A \mathcal{C} \otimes_A \mathcal{C},$$

and for any A-morphism  $f: X \to Y$ , the map

$$f \otimes I : X \otimes_A \mathcal{C} \to Y \otimes_A \mathcal{C}$$

is a comodule morphism.

### **3.3.** The category $\mathcal{M}^{\mathcal{C}}$ . Let $\mathcal{C}$ be an A-coring.

- The category M<sup>C</sup> has direct sums and cokernels.
   It has kernels provided C is flat as a left A-module.
- (2) For the functor  $-\otimes_A \mathcal{C} : \mathcal{M}_A \to \mathcal{M}^{\mathcal{C}}$  we have natural isomorphisms

 $\operatorname{Hom}^{\mathcal{C}}(M, X \otimes_{A} \mathcal{C}) \to \operatorname{Hom}_{A}(M, X), \quad f \mapsto (I \otimes \underline{\varepsilon}) \circ f,$ 

for  $M \in \mathcal{M}^{\mathcal{C}}$ ,  $X \in \mathcal{M}_A$ , with inverse map  $h \mapsto (h \otimes I) \circ \varrho_M$ , i.e., the functor  $- \otimes_A \mathcal{C} : \mathcal{M}_A \to \mathcal{M}^{\mathcal{C}}$  is right adjoint to the forgetful functor  $\mathcal{M}^{\mathcal{C}} \to \mathcal{M}_A$  and hence it preserves monomorphisms and products.

- (3) For the right comodule endomorphisms we have  $\operatorname{End}^{\mathcal{C}}(\mathcal{C}) \simeq \mathcal{C}^*$ .
- (4) C is a subgenerator in  $\mathcal{M}^{\mathcal{C}}$ .

*Proof.* (1) Consider a family  $\{M_{\lambda}\}_{\Lambda}$  of right *C*-comodules. It is easy to prove that the direct sum  $\bigoplus_{\Lambda} M_{\lambda}$  in  $\mathcal{M}_{A}$  is a right *C*-comodule and has the universal property of a coproduct in  $\mathcal{M}^{\mathcal{C}}$ .

For any morphism  $f: M \to N$  of right  $\mathcal{C}$ -comodules, the cokernel of f in  $\mathcal{M}_A$  has a comodule structure and hence is a cokernel in  $\mathcal{M}^{\mathcal{C}}$ . If  $\mathcal{C}$  is flat as a left A-module, similar arguments hold for the kernel.

(2) The proof of the corresponding assertion for coalgebras applies (e.g., [9, 3.12]) and then refer to 2.6. Note that the adjointness, for example, was also observed in [3, Lemma 3.1].

(3) The group isomorphism  $\operatorname{End}^{\mathcal{C}}(\mathcal{C}) \simeq \mathcal{C}^*$  follows from (2) by putting  $M = \mathcal{C}$  and X = A. This is a ring isomorphism when writing the morphisms on the right.

(4) For any  $M \in \mathcal{M}^{\mathcal{C}}$ , there is an epimorphism  $A^{(\Lambda)} \to M$  in  $\mathcal{M}_A$ . Tensoring with  $\mathcal{C}$  yields an epimorphism  $A^{(\Lambda)} \otimes_A \mathcal{C} \to M \otimes_A \mathcal{C}$  in  $\mathcal{M}^{\mathcal{C}}$ . As easily checked the structure map  $\varrho_M : M \to M \otimes_A \mathcal{C}$  is a morphism in  $\mathcal{M}^{\mathcal{C}}$ and hence M is a subobject of a  $\mathcal{C}$ -generated comodule.

### 3.4. $\mathcal{M}^{\mathcal{C}}$ as Grothendieck category.

For an A-coring C the following are equivalent:

(a) C is a flat left A-module;

(b) every monomorphism in  $\mathcal{M}^{\mathcal{C}}$  is injective;

(c) the forgetful functor  $\mathcal{M}^{\mathcal{C}} \to \mathcal{M}_A$  respects monomorphisms.

If these conditions are satisfied,  $\mathcal{M}^{\mathcal{C}}$  is a Grothendieck category.

*Proof.*  $(a) \Rightarrow (b) \Leftrightarrow (c)$  are obvious.

 $(c) \Rightarrow (a)$  For any monomorphism  $f : N \to L$  in  $\mathcal{M}_A$ , the map  $f \otimes I : N \otimes_A \mathcal{C} \to L \otimes_A \mathcal{C}$  is a monomorphism in  $\mathcal{M}^{\mathcal{C}}$  (by 3.3(2)) and hence injective by assumption. This shows that  $- \otimes_A \mathcal{C} : \mathcal{M}_A \to \mathbb{Z}$ -Mod is exact and hence  $\mathcal{C}$  is a flat left A-module.

Now assume that (a)-(c) are satified. Then  $\mathcal{M}^{\mathcal{C}}$  is abelian and cocomplete. Since  $\mathcal{C}$  is a subgenerator it is routine to show that the subcomodules of  $\mathcal{C}^n$ ,  $n \in \mathbb{N}$ , form a generating set for  $\mathcal{M}^{\mathcal{C}}$ . Hence  $\mathcal{M}^{\mathcal{C}}$  is a Grothendieck category.

Every right C-comodule M allows a left \*C-module structure by

 $\neg : {}^*\mathcal{C} \otimes_{\mathbb{Z}} M \to M, \quad f \otimes m \mapsto (I \otimes f) \circ \varrho_M(m).$ 

With this structure any comodule morphisms  $M \to N$  is \*C-linear, i.e.

 $\operatorname{Hom}^{\mathcal{C}}(M,N) \subset \operatorname{Hom}_{*\mathcal{C}}(M,N),$ 

and hence  $\mathcal{M}^{\mathcal{C}}$  is a subcategory of  $*_{\mathcal{C}}\mathcal{M}$ . As shown in [3, Lemma 4.3],  $\mathcal{M}^{\mathcal{C}}$  can be identified with  $*_{\mathcal{C}}\mathcal{M}$  provided  $\mathcal{C}$  is finitely generated and projective as left *A*-module.

Notice that in any case C is a faithful \*C-module since  $f \rightarrow c = 0$  for all  $c \in C$  implies  $f(c) = \underline{\varepsilon}(f \rightarrow c) = 0$  and hence f = 0.

The question arises when, more generally,  $\mathcal{M}^{\mathcal{C}}$  is a full subcategory of  ${}^{*_{\mathcal{C}}}\mathcal{M}$ , i.e., when  $\operatorname{Hom}^{\mathcal{C}}(M, N) = \operatorname{Hom}_{{}^{*_{\mathcal{C}}}}(M, N)$ , for any  $M, N \in \mathcal{M}^{\mathcal{C}}$ . The answer is given in our main theorem:

## 3.5. $\mathcal{M}^{\mathcal{C}}$ as full subcategory of ${}_{*\mathcal{C}}\mathcal{M}$

For the A-coring C, the following are equivalent:

(a)  $\mathcal{M}^{\mathcal{C}} = \sigma[{}_{*\mathcal{C}}\mathcal{C}];$ 

(b)  $\mathcal{M}^{\mathcal{C}}$  is a full subcategory of  $*_{\mathcal{C}}\mathcal{M}$ ;

- (c) for all  $M, N \in \mathcal{M}^{\mathcal{C}}$ ,  $\operatorname{Hom}^{\mathcal{C}}(M, N) = \operatorname{Hom}_{*\mathcal{C}}(M, N)$ ;
- (d) C satisfies the  $\alpha$ -condition as left A-module;
- (e) every  $^{*}C$ -submodule of  $C^{n}$ ,  $n \in \mathbb{N}$ , is a subcomodule of  $C^{n}$ ;
- (f) C is locally projective as left A-module.

If these conditions are satisfied we have, for any family  $\{M_{\lambda}\}_{\Lambda}$  of right A-modules,

$$(\prod_{\Lambda} M_{\lambda}) \otimes_{A} \mathcal{C} \simeq \prod_{\Lambda}^{\mathcal{C}} (M_{\lambda} \otimes_{A} \mathcal{C}) \subset \prod_{\Lambda} (M_{\lambda} \otimes_{A} \mathcal{C}).$$

*Proof.* The implications  $(a) \Leftrightarrow (b) \Leftrightarrow (c) \Rightarrow (e)$  are obvious.

 $(a) \Rightarrow (d)$  By 3.4  $_{A}C$  is flat. For any  $N \in \mathcal{M}_{A}$  we prove the injectivity of the map

$$\alpha: N \otimes_A \mathcal{C} \to \operatorname{Hom}_{\mathbb{Z}}({}^*\mathcal{C}, N), \quad n \otimes c \mapsto [f \mapsto nf(c)].$$

Considering  $\operatorname{Hom}_{\mathbb{Z}}({}^{*}\mathcal{C}, N)$  and the right  $\mathcal{C}$ -comodule  $N \otimes_{A} \mathcal{C}$  as left  ${}^{*}\mathcal{C}$ -modules in the canonical way, we observe that  $\alpha$  is  ${}^{*}\mathcal{C}$ -linear. So for any right  $\mathcal{C}$ -comodule L we have the commutative diagram

where the first vertical isomorphism is obtained by assumption and 3.3,

$$\operatorname{Hom}_{*\mathcal{C}}(L, N \otimes_A \mathcal{C}) = \operatorname{Hom}^{\mathcal{C}}(L, N \otimes_A \mathcal{C}) \simeq \operatorname{Hom}_A(L, N),$$

and the second one by canonical isomorphisms

 $\operatorname{Hom}_{*\mathcal{C}}(L, \operatorname{Hom}_{\mathbb{Z}}(^{*}\mathcal{C}, N)) \simeq \operatorname{Hom}_{\mathbb{Z}}(^{*}\mathcal{C} \otimes_{*\mathcal{C}} L, N) \simeq \operatorname{Hom}_{\mathbb{Z}}(L, N).$ 

This shows that  $\operatorname{Hom}(L, \alpha)$  is injective and so (by 2.5) the corestriction of  $\alpha$  is a monomorphism in  $\mathcal{M}^{\mathcal{C}}$ . Since  ${}_{A}\mathcal{C}$  is flat this implies that  $\alpha$  is injective (by 3.4).

 $(e) \Rightarrow (a)$  First we show that every finitely generated module  $N \in \sigma[{}_{*\mathcal{C}}\mathcal{C}]$ is a  $\mathcal{C}$ -comodule. There exists some  ${}^{*\mathcal{C}}$ -submodule  $X \subset \mathcal{C}^n$ ,  $n \in \mathbb{N}$ , and an epimorphism  $h : X \to N$ . By assumption X and the kernel of h are comodules and hence N is a comodule.

Now for any  $L \in \sigma[{}_{*\mathcal{C}}\mathcal{C}]$  the finitely generated submodules are comodules and hence L is a comodule.

For any \* $\mathcal{C}$ -morphism in  $\sigma[{}_{*\mathcal{C}}\mathcal{C}]$ , the kernel is a \* $\mathcal{C}$ -submodule and hence a comodule. As easily verified this implies that monomorphisms and epimorphisms in  $\sigma[{}_{*\mathcal{C}}\mathcal{C}]$  are comodule morphisms and hence this is true for all morphisms in  $\sigma[{}_{*\mathcal{C}}\mathcal{C}]$ .

 $(d) \Leftrightarrow (f)$  follows by 2.3.

 $(d) \Rightarrow (e)$  We show that for right *C*-comodules *M*, any \**C*-submodule *N* is a subcomodule. For this consider the map

$$\rho_N: N \to \operatorname{Hom}_A({}^*\mathcal{C}, N), \ n \mapsto [f \mapsto f \neg n].$$

With the inclusion  $i: N \to M$ , we have the commutative diagram with exact lines

where all the  $\alpha$ 's are injective and  $\operatorname{Hom}({}^*\mathcal{C}, i) \circ \rho_N = \alpha_{M,\mathcal{C}} \circ \varrho_M \circ i$ . This implies  $(p \otimes I) \circ \varrho_M \circ i = 0$ , and by the kernel property,  $\varrho_M \circ i$  factors through  $N \to N \otimes_A \mathcal{C}$  thus yielding a  $\mathcal{C}$ -coaction on N.

The final assertion follows by 2.6 and the characterization of products in  $\sigma[{}_{*C}\mathcal{C}]$  (see 2.7).

As a corollary we can show when all \*C-modules are C-comodules. This includes the reverse conclusion of [3, Lemma 4.3] and extends [11, Lemma 33].

**3.6.**  $\mathcal{M}^{\mathcal{C}} = {}_{*\mathcal{C}}\mathcal{M}.$ For any A-coring  $\mathcal{C}$ , the following are equivalent: (a)  $\mathcal{M}^{\mathcal{C}} = {}_{*\mathcal{C}}\mathcal{M};$ 

- (b) the functor  $-\otimes_A \mathcal{C} : \mathcal{M}_A \to {}_{*\mathcal{C}}\mathcal{M}$  has a left adjoint;
- (c)  $_{A}C$  is finitely generated and projective;
- (d)  $_{A}C$  is locally projective and C is finitely generated as right  $C^{*}$ -module.

*Proof.*  $(a) \Rightarrow (b)$  and  $(c) \Rightarrow (d)$  are obvious.

 $(b) \Rightarrow (c)$  By 2.6,  $-\otimes_A C$  preserves monomorphisms (injective morphisms) and hence  $_A C$  is flat. Moreover we obtain, for any family  $\{M_\lambda\}_\Lambda$  in  $\mathcal{M}_A$ , the isomorphism

$$(\prod_{\Lambda} M_{\lambda}) \otimes_{A} \mathcal{C} \simeq \prod_{\Lambda} (M_{\lambda} \otimes_{A} \mathcal{C}),$$

which implies that  ${}_{A}\mathcal{C}$  is finitely presented (e.g., [8, 12.9]) and hence projective.

 $(d) \Rightarrow (a)$  Recall that  $\mathcal{C}^*$  is the endomorphism ring of the faithful module  $*_{\mathcal{C}}\mathcal{C}$ . Hence  $\mathcal{C}_{\mathcal{C}^*}$  finitely generated implies  $\mathcal{M}^{\mathcal{C}} = \sigma[*_{\mathcal{C}}\mathcal{C}] = *_{\mathcal{C}}\mathcal{M}$  (see 2.7).  $\Box$ 

Acknowledgement. The author is very grateful to Jawad Abuhlail for interesting and helpful discussions on the subject.
